Implicit Parallel Programming in *pH* Rishiyur Nikhil, Arvind

Parallel machines are now affordable and available to many users in the form of small symmetric shared-memory multiprocessors (SMPs). Unfortunately, programming practices have not kept pace with this hardware advance. The vast majority of developers still write applications in sequential programming languages that do not exploit multiple processors. The traditional approaches for adding parallelism to applications are prone to introducing new, strange, and difficult-to-eliminate bugs.

In this important new text, the authors offer a completely different vision of the future, where parallel programming is the default and sequential programming is a special case. The foundation of this vision is an implicitly parallel programming language, *pH*, which is the result of two decades of research by the authors. A dialect and extension of the standard nonstrict and purely functional language Haskell, *pH* is essentially Haskell with implicitly parallel semantics. *pH*'s extensions to Haskell comprise a disciplined approach to shared parallel state, so that a *pH* program—even a beginner's program—is implicitly parallel.

The authors have developed this text over ten years while teaching implicit parallel programming to graduate students at MIT and specialized short courses to undergraduates and software professionals in the U.S., Japan, and India.

- * Provides a complete treatment of the language, the programming philosophy it embraces, and its theoretical underpinnings.
- * Includes many clear yet small examples.
- * Features programs, problems, solutions, and a downloadable *pH* implementation for SMP machines and related software.
- * Is designed for students and professionals with a thorough knowledge of a high-level programming language but with no previous experience in parallel programming.
